

SO 1: Draw the disk structure

Disk Structure

□ Magnetic Disks

- One or more **platters** in the form of disks covered with magnetic media.
- Each platter has two working **surfaces**
- Each working surface is divided into a number of concentric rings called **tracks**
- The collection of all tracks that are at the same distance from the edge of the platter is called a **cylinder**
- Each track is further divided into **sectors**
- The data on a hard drive is read by read-write **heads**
- Each head is on a separate **arm**, and controlled by a common **arm assembly**

Disk Structure (cont...)

- Disk drives are addressed as large 1-dimensional arrays of logical blocks, where the logical block is the smallest unit of transfer.
- The 1-dimensional array of logical blocks is mapped into the sectors of the disk sequentially.
 - Sector 0 is the first sector of the first track on the outermost cylinder.
 - Mapping proceeds in order through that track, then the rest of the tracks in that cylinder, and then through the rest of the cylinders from outermost to innermost.

FAT

Disk Structure (cont...)

- The rate at which data can be transferred from the disk to the computer is composed of several steps:
 - **Seek time** or **random access time** is the time required to move the heads from one cylinder to another, and for the heads to settle down after the move
 - The **rotational latency** is the amount of time required for the desired sector to rotate around and come under the read-write head
 - The **transfer rate**, which is the time required to move the data electronically from the disk to the computer

SO 2: Demonstrate the disk scheduling algorithms

Disk Scheduling

- ❑ The operating system is responsible for using hardware efficiently — for the disk drives, this means having a fast access time and disk bandwidth.
- ❑ Access time has two major components
 - ❑ Seek time is the time for the disk arm to move the heads to the cylinder containing the desired sector.
 - ❑ Rotational latency is the additional time waiting for the disk to rotate the desired sector to the disk head.
- ❑ Minimize seek time
- ❑ Disk bandwidth is the total number of bytes transferred, divided by the total time between the first request for service and the completion of the last transfer.

Disk Scheduling (Cont.)

- Several algorithms exist to schedule the servicing of disk I/O requests.
- We illustrate them with a request queue (0-199).

98, 183, 37, 122, 14, 124, 65, 67

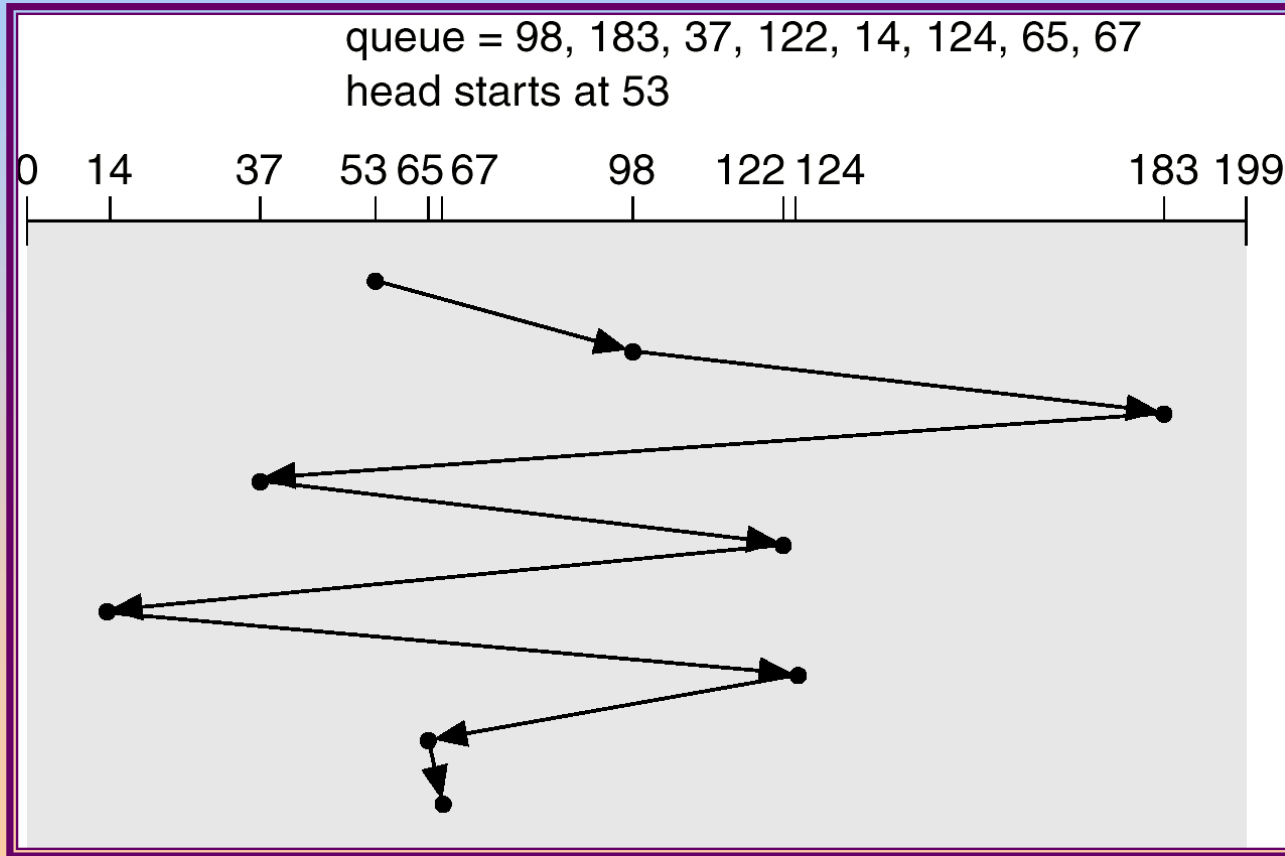

Head pointer 53

FCFS

Illustration shows total head movement of 640 cylinders.

SSTF

- ❑ Selects the request with the minimum seek time from the current head position.
- ❑ SSTF scheduling is a form of SJF scheduling; may cause starvation of some requests.
- ❑ Illustration shows total head movement of 236 cylinders.

SSTF (Cont.)

SCAN

- ❑ The disk arm starts at one end of the disk, and moves toward the other end, servicing requests until it gets to the other end of the disk, where the head movement is reversed and servicing continues.
- ❑ Sometimes called the *elevator algorithm*.
- ❑ Illustration shows total head movement of 208 cylinders.

SCAN (Cont.)

C-SCAN

- ❑ Provides a more uniform wait time than SCAN.
- ❑ The head moves from one end of the disk to the other, servicing requests as it goes. When it reaches the other end, however, it immediately returns to the beginning of the disk, without servicing any requests on the return trip.
- ❑ Treats the cylinders as a circular list that wraps around from the last cylinder to the first one.

C-SCAN (Cont.)

C-LOOK

- Version of C-SCAN
- Arm only goes as far as the last request in each direction, then reverses direction immediately, without first going all the way to the end of the disk.

C-LOOK (Cont.)

Selecting a Disk-Scheduling Algorithm

- ❑ SSTF is common and has a natural appeal
- ❑ SCAN and C-SCAN perform better for systems that place a heavy load on the disk.
- ❑ Performance depends on the number and types of requests.
- ❑ Requests for disk service can be influenced by the file-allocation method.
- ❑ The disk-scheduling algorithm should be written as a separate module of the operating system, allowing it to be replaced with a different algorithm if necessary.
- ❑ Either SSTF or LOOK is a reasonable choice for the default algorithm.

SO 3: Summarize the steps in disk management

Disk Management

- ❑ Low-level formatting, or physical formatting — Dividing a disk into sectors that the disk controller can read and write.
- ❑ To use a disk to hold files, the operating system still needs to record its own data structures on the disk.
 - ❑ Partition the disk into one or more groups
 - ❑ Logical formatting or “making a file system”.
- ❑ Boot block initializes system.
 - ❑ The bootstrap is stored in ROM.
 - ❑ Bootstrap loader program.

Bad block

- ❑ Methods such as sector sparing and sector slipping are used to handle bad blocks.
